# Subgenera of *Enoploteuthis*, *Abralia* and *Abraliopsis* of the Squid Family Enoploteuthidae (Cephalopoda, Oegopsida)

By

#### Kotaro TSUCHIYA and Takashi OKUTANI

Tokyo University of Fisheries, Tokyo

Abstract The subgenera in three genera of oegopsid squid family Enoploteuthidae (Enoploteuthis, Abralia and Abraliopsis) are revised. The genus Enoploteuthis contains two subgenera, Enoploteuthis s. str. and Paraenoploteuthis nov. The former subgeneric arrangement of the genus Abralia is changed. It is divisible into five subgenera, namely, Abralia s. str., Astrabralia, Asteroteuthis, Pygmabralia, and Heterabralia nov. The genus Abraliopsis consists of four subgenera, Abraliopsis s. str., Micrabralia, Boreabraliopsis nov., and Pfefferiteuthis nov. Relationships among genera and subgenera of the family are discussed.

Several subgenera of the Family Enoploteuthidae have been proposed since earlier studies of PFEFFER (1900, 1912) and CHUN (1900), and recently by NESIS (1987). During the course of the extensive taxonomic studies on the enoploteuthid squids, mainly from the North Pacific, it became clear that the genera *Enoploteuthis*, *Abralia* and *Abraliopsis* are reasonably divisible into subgenera or at least species-groups that are critically revised here. Those subgeneric names are chronologically arranged in the following lines.

The genera Watasenia ISHIKAWA, 1913, and Enigmoteuthis ADAM, 1973 were established by monotypy, and they are not necessary to be revised herewith.

#### I. Subgenera of the Genus Enoploteuthis

The grouping of the species in the genus *Enoploteuthis* seems to have first been attempted by ROPER (1966). Later, BURGESS (1982) recognized the two speciesgroups, *leptura*-complex and *anapsis*-complex, based on the tentacular characters, such as the degree of prominency of club, the size of manus hooks, the dactylus sucker arrangement, and the shape of carpus. The more critical definition is given here basically to follow BURGESS's scheme (Table 1).

# 1. Subgenus Enoploteuthis D'Orbigny, 1848 (s. str.)

Type species: Loligo leptura LEACH, 1817.

Diagnosis: Body is rather large. Right ventral arm of the male is hectocotylized. Hectocotylus is composed of a single ventral flap. Many small papillae are present on

#### Kotaro Tsuchiya and Takashi Okutani

Table 1.	An abridged comparison of selected criteria of two subgenera of	
	the genus Enoploteuthis.	

	Enoploteuthis s. s.	Paraenoploteuthis nov
Oral surface of arms	Papillated	Normal
Hectocotylization	1 flap	2 flaps
Tentacle:		
Club	Very narrow	Expanded
Carpal group	Elongate	Discoidal
Manus hooks	Subequal in size	Unequal in size
Dactylus suckers	2 rows	4 rows
Ventral flap	Absent	Present

the oral surfaces of the Arms I-III. Tentacle is short and weak. Ventral flap of the tentacle is absent. Fixing apparatus is elongate. Ventral hooks of manus are slightly larger than the dorsal hooks. Dactylus suckers are arranged in two longitudinal rows (Figs. 1-3).

#### Included species:

- 1. Enoploteuthis leptura (LEACH, 1817)
- 2. Enoploteuthis reticulata RANCUREL, 1970
- 3. Enoploteuthis obliqua Burgess, 1982
- 4. Enoploteuthis octolineata Burgess, 1982.

Geographical distribution: Warm waters of the world.

Remarks: This subgenus is easily separable from the other in having biserial dactylus sucker rows. The conical small papillae on the oral surfaces of the Arms I-III of E. leptura mentioned by ROPER (1966) are also present in the Pacific species, E. reticulata, E. obliqua and E. octolineata.

# 2. Subgenus Paraenoploteuthis nov.

Type species: Enoploteuthis chuni Ishikawa, 1914.

Disagnosis: Right ventral arm of the male is hectocotylized. In the hectocotylized arm, a pair of different sized, offset crests are prominent, of which the distal one is situated on the dorsal margin and proximal one, on the ventral margin of the oral surface of the arm. Tentacle is long and robust. The ventral flap of tentacle is present. Fixing apparatus is oval in shape. Ventral hooks of the manus are larger than the dorsal hooks. Dactylus suckers are arranged in four longitudinal rows (Figs. 4-5).

#### Included species:

- 1. Enoploteuthis chuni Ishikawa, 1914 syn. E. theragrae Taki, 1964
- 2. Enoploteuthis galaxias BERRY, 1918
- 3. Enoploteuthis anapsis ROPER, 1964
- 4. Enoploteuthis jonesi Burgess, 1982
- 5. Enoploteuthis higginsi Burgess, 1982.

Figs. 1-3. Enoploteuthis (s.s.) reticulata RANCUREL, 1970, male (99.1 mm DML) from Uraga Channel, 700 m wire paid-out (Soyo-Maru, 1957). — 1. Left Arm I. 2. Right tentacle. 3. Hectocotylized arm.

Figs. 4-5. Enoploteuthis (Paraenoploteuthis nov.) chuni Ishikawa, 1914, male (76.7 mm DML) from 30°04.6′ N, 134°27.9′E, 530-560 m (Kaiyo-Maru, 1986). — 4. Right tentacle. 5. Hectocotylized arm, oral and lateral views. [Scale bars: 5 mm.]

Geographical distribution: Warm to cool temperate waters of the Atlantic and Pacific.

Remarks: On the evaluation of the characters to split the genus *Enoploteuthis*, BURGESS (1982) considered that the presence or absence of the ventral flap of the carpus is one of the important criteria. RIDDELL (1985) described the presence of the ventral flap in *E. galaxias* from New Zealand waters. The papillation on the oral surfaces of arms characterizing the subgenus *Enoploteuthis* is not present in this subgenus.

# II. Subgenera of the Genus Abralia

The subgenera of the genus *Abralia* were studied by several authors (Pfeffer, 1900, 1912; Grimpe, 1931; Voss, 1954, 1963; Clarke, 1966; Nesis, 1982). The recent discoveries of several new species from the Indian Ocean (Okutani, 1983),

the Atlantic (Lipiński, 1983), and the Pacific (Voss, 1963; Okutani & Tsuchiya, 1987), as well as the present critical revision led a conclusion that the genus is divisible into five subgenera (Table 2). Nesis (1987) recently proposed a new system with six subgenera which is to some degree different from ours. The change of the subgenera from the previous works is summarized in Table 3.

1. Subgenus Abralia GRAY, 1849 (s. str.) emend.

Synonym: Stenabralia GRIMPE, 1931 (pars.).

Type species: Onychoteuthis armata Quoy et GAIMARD, 1832.

Diagnosis: Body is medium to large for the genus. Suckers of the distal portion of the Arms I-III are tri- or quadriserial in adult. Right ventral arm of the male is hectocotylized. Tentacular hooks are more than five in number. Subocular photophores are composed of ovoid, orange-colored mesial organs and elongate, opaque terminal ones (Figs. 6-8).

# Included species:

- 1. Abralia armata (Quoy et GAIMARD, 1832)
- 2. Abralia steindachneri WEINDL, 1912
- 3. Abralia multihamata SASAKI, 1929 syn. A. lucens Voss, 1963
- 4. Abralia renschi GRIMPE, 1931

# 5. Abralia spaercki Grimpe, 1931 syn. A. armata sensu Voss, 1963.

Geographical distribution: Indo-Pacific.

Remarks: Abralia armata (Quoy et Gaimard, 1832), was described based on a single young specimen from Celebes, and its original description was so short that the taxonomic characters were not satisfactorily understood. Later, Voss (1963) redescribed A. armata based on the specimens identified by Grimpe (1931) from the Philippines. According to Quoy and Gaimard (1832), A. armata is characterized in having six tentacular hooks and biserial rows of distal arm suckers. The holotype specimen of A. armata in the Muséum National d'Histoire Naturelle, Paris, is only a gladius (P. Bouchet, pers. comm.).

GRAY (1849) established the genus Abralia based on Onychoteuthis armata. GRIMPE (1931) created the subgenus Stenabralia in the genus Abralia, and species with more than four tentacular hooks were allocated therein. GRIMPE (1931) and CLARKE (1966) considered that the subgenus Stenabralia contains six species, namely, A. astrolineata BERRY, 1914, A. astrosticta BERRY, 1919, A. lucens Voss, 1963, A. renschi GRIMPE, 1931, A. spaercki GRIMPE, 1931, and A. steindachneri WEINDL, 1912.

Among them, Abralia astrolineata BERRY, 1914, and Abralia astrosticta BERRY, 1909, are readily separable from A. armata in having the characteristic terminal photophores on the Arm IV in young stage, and from the other species of Stenabralia in having only five monotypic subocular photophores without opaque terminal organs. These two species should be placed in the other subgenus.

Abralia renschi GRIMPE, 1931, is a medium-sized species characterized in having five to seven tentacular hooks and two types of six subocular photophores. This species is easily separable from A. armata by the distinctly and regularly longitudinal arrangement of photophores on the mantle.

Abralia steindachneri Weindl, 1912, and Abralia lucens Voss, 1963, are large-sized species characterized in having five to six tentacular hooks and two types of six to eight subocular photophores, and tri- or quadriserial rows of distal arm suckers.

Abralia spaercki Grimpe, 1931, was first allocated in the subgenus Abralia s. str. by Grimpe (1931), but later, Voss (1963) moved it to the subgenus Stenabralia. It is characterized by having six to seven tentacular hooks, two types of six to eight subocular photophores, and tri- or quadriserial rows of distal arm suckers. It is separable from the other species by possession of a pair of peculiar photophores in the funnel groove.

Abralia armata sensu Voss, 1963, has six tentacular hooks, two types of five to seven subocular photophores, biserial sucker rows at the distal tip of the Arms I–III and large "photogenic organ" on the ventral surface of the ink-sac. Voss described this organ that "the sac is broadly oval and black, but extending across the ventral surface and up the sides laterally is a distinctly demarcated bronze and pearly iridescent layer which appears to be similar to the luminous light organs found on the ink-sac in some other groups." It means that this organ is neither granular nor lens-bearing.

Such an iridescent layer overlying the intestine is commonly observed in young stages of several forms of *Abralia*, as well as other families, such as Cranchiidae. This fact suggests that *A. armata* observed by Voss (1963) was a young stage. This assumption may be corroborated by the facts that his specimens had a short and plump mantle, indistinct nuchal crests, premature carpus, and weak, slender and elongate arms. These are all characters usually observed in young enoploteuthids. A specimen illustrated by Voss (Figure 18a) has three pairs of photophores on the dorsal surface of fins. This character suggests that his specimens were most probably young specimens of *A. spaercki*. A peculiar photophore in the funnel groove seem to be overlooked by him.

A Formosan species, Abralia multihamata SASAKI, 1929, is characterized by six to seven tentacular hooks, two types of six subocular photophores, and biserial rows of distal arm suckers. The peculiar photophores in the funnel groove are not recognized by SASAKI (1929, text-fig. 173B). It suggests that A. multihamata is probably a young stage of A. lucens. The photophores on the dorsal fins were never described by SASAKI (1929) and not able to be compared with A. lucens.

Therefore, it is assumed that the species hitherto being included in the subgenus Abralia, viz. A. armata and A. multihamata, represent young specimens of the species that have hitherto been assigned to Stenabralia. A definition of the subgenus Stenabralia given by GRIMPE (1931) is only that Abralia with a narrow fin and more than four tentacular hooks. Abralia GRAY, 1849, has a priority to Stenabralia GRIMPE, 1931, which is thus synonymous with the former. Although GRIMPE (1931) considered that A. (Abralia) multihamata is conspecific with A. armata. Nesis (1987) placed it in the subgenus Asteroteuthis.

#### 2. Subgenus Asteroteuthis Pfeffer, 1908

Type species: Abralia veranyi (RÜPPELL, 1844).

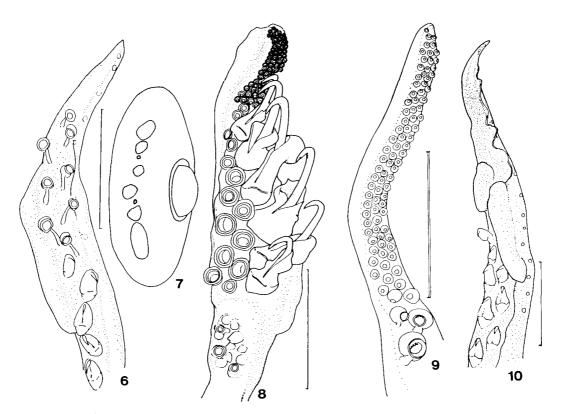

Diagnosis: Body is medium in size. Suckers of the distal portion of the Arms I–III are tri- or quadriserial. Left ventral arm of the male is hectocotylized. Tentacular hooks are three to five in number. Subocular photophores are composed of ovoid, orange-colored mesial organs and elongate, opaque terminal ones (Figs. 9–10).

Included species:

1. Abralia veranyi (RÜPPELL, 1844).

Geographical distribution: Atlantic.

Remarks: GRIMPE (1931) allocated Abralia japonica ISHIKAWA, 1929, in the subgenus Asteroteuthis. A. japonica is believed to be a large-sized species characterized by having two large tentacular hooks, three small carpal suckers, and five monotypic subocular photophores, and this is known by only two females from the type locality, Uwozu, Toyama Bay, Japan Sea (ISHIKAWA, 1929). ISHIKAWA (1929) identified this species to be the genus Abralia based on the possessions of uniserial hooks on the tentacular club and absence of terminal photophores at the tip of the Arm IV. However, he described that "the buccal membrane deep violet" and, "all these arms bear

Figs. 6-7. Abralia (s. s.) multihamata SASAKI, 1929. — 6. Male (38.5 mm DML) from the East China Sea, immature hectocotylized arm (Yoko-Maru). 7. Female (28.8 mm DML) from Suruga Bay, 10 m deep, right eyeball (NSMT-Mo 62339).

Fig. 8. Abralia (s. s.) spaercki GRIMPE, 1931, female (56.0 mm DML) from 27°13.2′S, 153°52.6′E, 500–540 m, left tentacle (NMV F51777).

Figs. 9-10. Abralia (Asteroteuthis) veranyi (RÜPPELL, 1844), male (36.3 mm DML) from 7°40'N, 54°12'W, 402 m deep (NSMT-Mo 61080). — 9. Distal part of the left Arm I. 10. Hectocotylized arm. [Scale bars: 5 mm (simple) or 2 mm (double).]

small stout hooks in two alternating rows, replaced by some two series of suckers at the extremity, except on the tip of the ventral arm." These two characters never match with those of the genus Abralia. Very small carpal sucker and absence of sucker on the Arm IV are characters of genera Watasenia and Abraliopsis, although two characters, namely, the absence of carpal flap and the absence of terminal photophores on the Arm IV contrarily do not match with both genera. Although ISHIKAWA (1929) mentioned the terminal photophores that "this absence of the organ is neither to be looked upon as the result of an accident nor as due to a secondary of ontogenetic circumstance," the absence of terminal photophores will be due to malformation or artificial defect. The carpal flap is often unnoticed. Also none of specimen has been re-discovered since the original description, in spite of the fact that more than several thousands of Watasenia scintillans have hitherto been examined by many previous authors through a long history of fishery biological investigations on this squid and by ourselves for the present study. We consider Abralia japonica to be

an abnormal specimen of Watasenia scintillans.

# 3. Subgenus Astrabralia Nesis, 1987

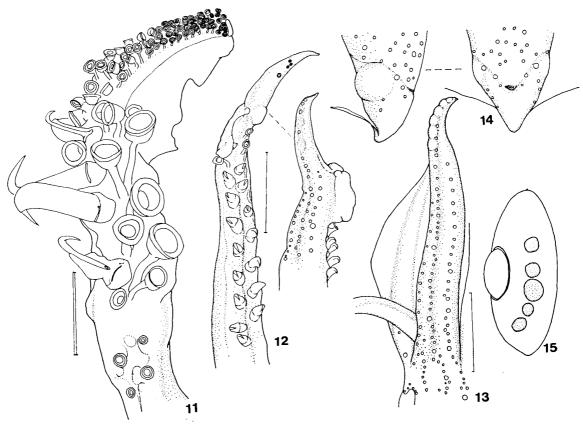

Synonyms:

Compsoteuthis, Pfeffer, 1912 (pars.)

Stenabralia GRIMPE, 1931 (pars.).

Type species: Abralia astrosticta Berry, 1909.

Diagnosis: Body is large. Suckers of the distal portion of the Arms I–III are biserial. Right ventral arm of the male is hectocotylized with a slightly bilobed proximal crest and a lunate distal crest. On the terminal portion of the Arm IV is a row of large hemispherical photophores. A pair of photophores is embedded on the lateral sides of the tail. Tentacular hooks is more than five in number. Subocular photophores are composed of only ovoid orange-colored monotypic organs without elongate

Figs. 11-12. Abralia (Astrabralia) astrosticta BERRY, 1909, male (46.0 mm DML) from 21°36.5′ N, 158°11.5′W, 58 fms. (USNM 730628). —— 11. Right tentacle. 12. Hectocotylized arm, oral and lateral views.

Figs. 13-15. Abralia (Astrabralia) astrosticta Berry, 1909, young female (41.1 mm DML) from 32°47.3′N, 147°58.7′E, 0-120 m (Kaiyo-Maru, 1987). —— 13. Right arm IV, aboral view. 14. Caudal photophores, lateral and ventral views. 15. Right eyeball. [Scale bars: 5 mm (simple) or 2 mm (double).]

opaque one. Photophores on the mantle is arranged in regular rows (Figs. 11–15). Included species:

- 1. Abralia astrosticta Berry, 1909
- 2. Abralia astrolineata Berry, 1914.

Geographical distribution: Pacific.

Remarks: This subgenus is easily separable from the other subgenera by the presence of a row of the large terminal photophores on the Arm IV, which are probably homologous with the photophores in the genera *Abraliopsis* and *Watasenia*, though these terminal photophores are neither swollen nor pigmented unlike terminal organs of those genera.

Voss (1955) regarded the subgenus *Compsoteuthis* as an invalid name because terminal photophores were not mentioned by Pfeffer (1912) and Berry (1914b), nor present in a mature specimen (57.0 mm DML) in Voss's collection. These terminal photophores become indistinct with growth. (They are drawn as the white tubercles in Berry, 1914b, pl. 51, fig. 1). Another species included in the present subgenus, *Abralia astrolineata* has the same organs which are distinct in young stage (RIDDELL, 1985).

# 4. Subgenus Pygmabralia NESIS, 1987

Type species: Abralia redfieldi Voss, 1955.

Diagnosis: Body is small to medium. Suckers of the distal portion of the Arms I-III are biserial. Right ventral arm of the male is hectocotylized with a bilobed proximal flap. Number of tentacular hooks is less than four. Subocular photophores are composed of only ovoid, orange-colored monotypic organs without elongate opaque one (Figs. 19–21).

Included species:

- 1. Abralia redfieldi Voss, 1955
- 2. Abralia grimpei Voss, 1958
- 3. Abralia marisarabica Okutani, 1983
- 4. Abralia similis OKUTANI et TSUCHIYA, 1987.

Geographical distribution: Atlantic and Indo-Pacific.

Remarks: This subgenus is very close to the subgenera Asteroteuthis and Heterabralia nov. in the body proportion and the number of tentacular hooks, but distinguishable from them by the right ventral arm hectocotylized. It is also different from them in having a bilobed proximal crest in the modified portion of hectocotylized arm and absence of any elongated opaque terminal subocular photophores.

This subgenus is also distinguishable from the subgenus *Abralia* s. str. in having only the monotypic subocular photophores and biserial arm sucker arrangement.

NESIS (1987) established the subgenus Arabralia based on A. marisarabica, while it cannot be splitted from the present subgenus by the characters of terminal suckers of the arms, morphology of hectocotylized arm, number of tentacular hooks, and composition of subocular photophores.

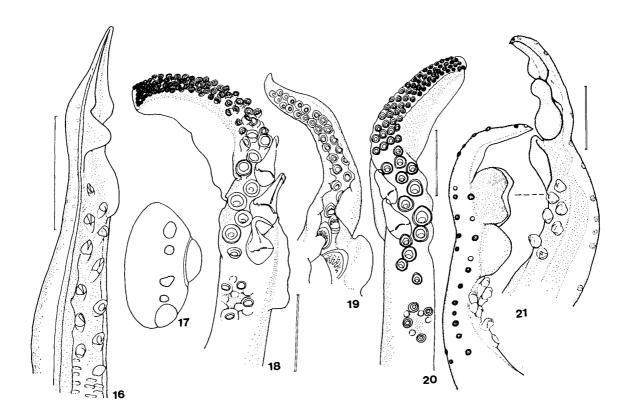

Abralia grimpei Voss, 1958, was classified by Nesis (1983, 1987) into the subgenus Asteroteuthis, while it should be transferred to the present subgenus because of having monotypic subocular photophores.

# 5. Subgenus Heterabralia nov.

Synonym: Asteroteuthis Pfeffer, 1908 (pars.).

Type species: Abralia and amanica GOODRICH, 1896.

Diagnosis: Body is medium in size. Suckers of the distal portion of the Arms I-III are biserial. Left ventral arm of the male is hectocotylized. Tentacular hooks are less than four in number. Subocular photophores are composed of ovoid, orange-colored mesial organs and elongate, opaque terminal ones (Figs. 16-18).

Figs. 16–18. Abralia (Heterabralia, nov.) robsoni Grimpe, 1931. —— 16. Male (38.0 mm DML) from the East China Sea, 0–310 m, hectocotylized arm (Yoko-Maru). 17, Female (48.2 mm DM) from off Odawara, Sagami Bay, left eyeball (Soyo-Maru, 1973). 18. Female (49.0 mm DML) from off Odawara, Sagami Bay, left tentacle (Soyo-Maru, 1973).

Figs. 19-21. Abralia (Pygmabralia) similis Okutani et Tsuchiya, 1987. —— 19. Female (32.4 mm DML) from 30°04.6′N, 134°27.9′E, 0-560 m, distal portion of the Arm II (NSMT-Mo 66645). 20. Male (18.6 mm DML) from 30°03.2′N, 134°03.5′E, 0-550 m, right tentacle (NSMT-Mo 66642: Holotype). 21. Male (17.7 mm DML) from 30°04.5′N, 143°46.6′E, 500-900 m, hectocotylized arm, two different views (NSMT-Mo 66644). [Scale bars: 5 mm (simple) or 2 mm (double).]

# Included species:

- 1. Abralia andamanica GOODRICH, 1896
- 2. Abralia trigonura BERRY, 1913
- 3. Abralia robsoni Grimpe, 1931
- 4. Abralia siedleckyi Lipiński, 1983.

Geographical distribution: Indo-Pacific.

Remarks: This new subgenus contains the almost all atypical species of the genus Asteroteuthis sensu GRIMPE, 1931. These species are different from Asteroteuthis typified by A. veranyi in having biserial suckers in the Arms I-III versus tri- or quadriserial suckers.

# III. Subgenera of the Genus Abraliopsis

The genus Abraliopsis was hitherto divided into two subgenera, Abraliopsis Joubin, 1896 (s. str.) and Micrabralia Pfeffer, 1900. In the present study, two new subgenera are separated from them based on the characters of hectocotylus and tentacle (Table 4).

Table 4. An abridged comparison of selected criteria of four subgenera of the genus *Abraliopsis*.

	Abraliopsis s. s.	Micrabralia	Boreabraliopsis nov.	Pfefferiteuthis nov.
Oral surface of arms	Smooth	Papillated	Smooth	Papillated
Hectocotylization	Subequal flaps	Subequal flaps	Unequal flaps	Subequal flaps
Left Arm IV of male	Normal	Normal	Normal	Modified
Ventral flap of manus	Absent	Present/Absent	Present	Present/Absent
Photophore arrangement on head	Scattered	Linear	Scattered	Linear

# 1. Subgenus Abraliopsis Joubin, 1896 (s. str.)

Synonym: Abralia Pfeffer, 1912 (pars.).

Type species: Abraliopsis pfefferi Joubin, 1896.

Diagnosis: Photophores on the ventral surface of the head are uniformly scattered. Hectocotylus is composed of two different-sized, offset crests. Protective membrane of the left Arm IV of the male is not modified. Tentacular club has the ventral flap (Figs. 22–23).

# Included species:

- 1. Abraliopsis hoylei (Pfeffer, 1884)
- 2. Abraliopsis pfefferi Joubin, 1896
- 3. Abraliopsis tui RIDDELL, 1985
- 4. Abraliopsis n. sp. A.

Geographical distribution: Warm waters of the world.

Remarks: Subgenus Abraliopsis sensu Pfeffer, 1900, is divisible into two subgenera. This subgenus is characterized by the presence of ventral flap and well-

developed aboral keel of the tentacular club, and the hectocotylus composed of two irregular-sized offset crests.

# 2. Subgenus Micrabralia Pfeffer, 1900

Type species: Abralia lineata GOODRICH, 1896.

Diagnosis: Photophores on the ventral surface of the head form distinct longitudinal rows: two continuous crests on the ventral margin and one on the dorsal margin. Hectocotylus in right Arm IV is composed of three subequal-sized offset crests. Protective membranes of the left Arm IV, of which oral surface is smooth, are not modified. The protective membrane of the Arms I–III of the male is somewhat developed than that of the Arm IV and their oral surface is ornamented by many conical papillae.

Included species:

- 1. Abraliopsis affinis (Pfeffer, 1912)
- 2. Abraliopsis gilchristi (Robson, 1924).

Geographical distribution: Indian Ocean and South Pacific.

Remarks: This subgenus is characterized by the distinct longitudinal photophore rows on the ventral head, and the presence of ventro-distal crest in the hectocotylus. The papillation on the oral surfaces of the Arms I–III of the male (Voss, 1967; RIDDELL, 1985) is a remarkable character by which this subgenus is distinguished from the subgenera *Abraliopsis* s.s. and *Boreabraliopsis* nov. The left Arm IV of the male of the present subgenus is not modified to a fleshy web (Voss, 1967; Nesis, 1982) unlike *Pfefferiteuthis* nov. and lacks conical papillae on its oral surface (Voss, 1967).

# 3. Subgenus Boreabraliopsis nov.

Synonym: Watasenia McGowan & Okutani, 1968, non Ishikawa, 1913.

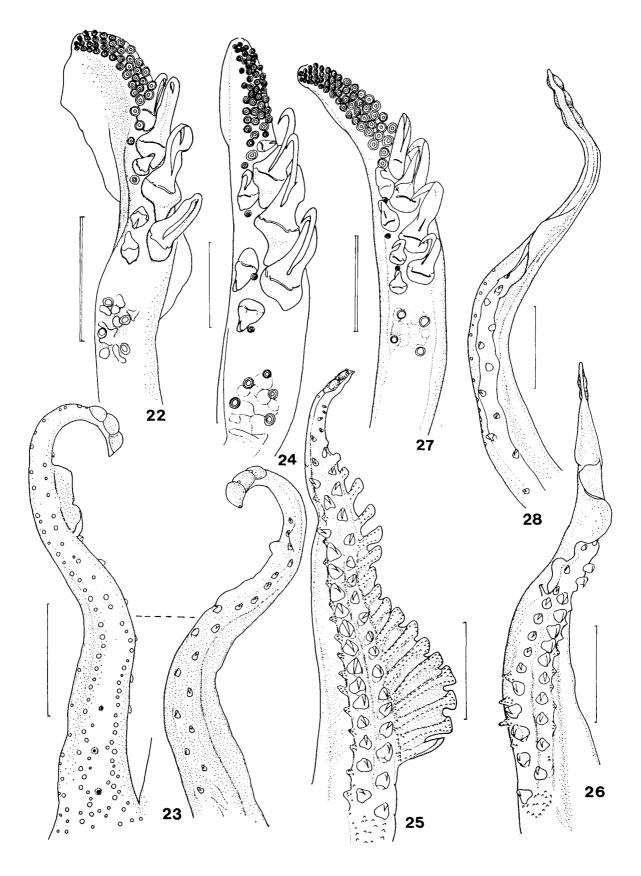

Type species: Abraliopsis felis McGowan et Okutani, 1968.

Definition: Photophores on the ventral surface of the head is uniformly scattered. Hectocotylus is composed of two subequal-sized offset crests. Protective membrane of the left Arm IV in male is not modified. Tentacular club lacks ventral flap (Figs. 27–28).

Figs. 22–23. Abraliopsis (s. s.) sp. A, male (24.9 mm DML) from 36°04.5'N, 157°55.6'E, 150–300 m (Kaiyo-Maru, 1972). — 22. Left tentacle. 23. Hectocotylized arm, oral and lateral views.

Figs. 24–26. Abraliopsis (Pfefferiteuthis nov.) falco Young, 1972, male (32.5 mm DML) from 30°04.2′N, 134°28.0′E, 0–650 m (Kaiyo-Maru, 1986). — 24. Left tentacle. 25. Modified left Arm IV. 26. Hectocotylized arm (right Arm IV).

Figs. 27–28. Abraliopsis (Boreabraliopsis nov.) n. sp. B. — 26. Female (33.1 mm DML) from 32°28.8′N, 149°58.2′E, 0–100 m, left tentacle (Kaiyo-Maru, 1987). 28. Male (43.3 mm DML) from 37°32.5′N, 147°59.5′E, 0–101 m, hectocotylized arm (Kaiyo-Maru, 1987). [Scale bars: 5 mm (simple) or 2 mm (double).]

# Included species:

- 1. Abraliopsis felis McGowan & Okutani, 1968
- 2. Abraliopsis n. sp. B.

Geographical distribution: Warm to cool temperate waters of the Pacific.

Remarks: This new subgenus is characterized by the absence of ventral flap and narrow aboral keel of the tentacular club, and the hectocotylus composed of two subequal-sized offset crests.

# 4. Subgenus Pfefferiteuthis nov.

Synonym: Micrabralia Pfeffer, 1912 (pars.) nec 1900. Type species: Abralia (Micrabralia) affinis Pfeffer, 1912.

Diagnosis: Photophores on the ventral surface of the head form distinct longitudinal rows. Hectocotylus in right Arm IV is composed of three subequal sized offset crests: two continuous crests on the ventral margin and one on the dorsal margin. Protective membranes of the left Arm IV are modified into a wide fleshy web, and its oral surface is ornamented by many small conical papillae which are also pronounced on the proximal oral surface of the male's Arms I–III (Figs. 24–26).

# Included species:

- 1. Abraliopsis affinis (PFEFFER, 1912)
- 2. Abraliopsis falco Young, 1972
- 3. Abraliopsis chuni NESIS, 1982
- 4. Abraliopsis atlantica Nesis, 1982.

Geographical distribution: Northwest to East Pacific and Atlantic Ocean.

Remarks: The subgenus *Micrabralia* sensu Pfeffer, 1912, is divisible into two subgenera. The present new subgenus is characterized by the distinct longitudinal photophore rows on the ventral head, presence of the ventro-distal crest in the hectocotylus and papillation on the oral surfaces of all arms in male (Hoyle, 1904; Chun, 1910; Young, 1972). In addition, the modification of the fleshy web of the left Arm IV of the male is a remarkable character that distinguishes the present new subgenus from *Micrabralia* (Hoyle, 1904; Chun, 1910; Young, 1972; Nesis, 1982).

#### **Conclusive Remarks**

The phylogenic relationship of the family Enoploteuthidae have never been discussed until the recent works of Engeser and Clarke (1988) and Young and Bennet (1988). Among the genera of this family, *Enoploteuthis* has hitherto been placed at the most primitive position and the genera *Abralia* and *Abraliopsis* in the advanced ones. Nesis (1987) discussed the process of "oceanization" in relation to phylogenetic advancement in order of *Enoploteuthis*, *Enigmoteuthis*, *Abralia*, *Watasenia* and *Abraliopsis*. His scheme matched well with the conventional view. Engeser and Clarke (1988) discussed the phylogenic relationship with out-groups such as Onychoteuthidae based on the characters of hooks. They considered that *Abraliopsis* and *Abralia* are more advanced than *Enoploteuthis*. Young and Bennet (1988) placed *Abralia* in the most

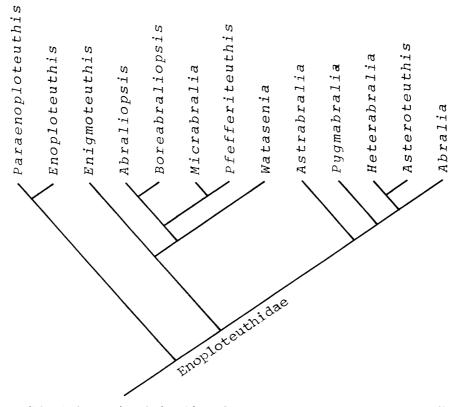

Fig. 29. Possible phylogenetic relationships of genera and subgenera of the Family Enoploteuthidae.

primitive status with *Enoploteuthis* which is derived from the stem of the former, *Abraliopsis* is considered to be the most advanced while *Watasenia* is less advanced than that based on the structure of integumental photophores.

In the present study, 25 characters are subjected to analysis (TSUCHIYA, unpublished), and the result is here tentatively given in form of a dichotomous tree of the genera and subgenera of the Family Enoploteuthidae (Fig. 29).

#### Acknowledgements

In accomplishment of the present study, we owe kindness and efforts of many persons and institutions. We extend our gratitude to Captains and crews of the R/V Kaiyo-Maru and the other research vessels as well as scientists on board for their greatest effort of sampling oceanic biological specimens on which this study was based. Mr. M. J. Sweeney (U. S. National Museum of Natural History, Washington), Dr. C. C. Lu (Museum of Victoria, Melbourne), Dr. J. Knudsen (Zoological Museum, Copenhagen) and Dr. T. Kubodera (National Science Museum, Tokyo) all kindly arranged for the loan of type and non-type specimens under their care. Dr. R. E. Young, University of Hawaii, kindly offered us gifts and loan of the good specimens from Hawaiian waters. Dr. T. Kubota, Tokai University, Dr. Y.

SHOJIMA, Seikai Regional Fisheries Research Laboratory, Nagasaki, and many more persons offered specimens for reference.
